1. Introduction and Background

Blue Minerals Consultancy of Australia, Buka Environmental of the United States, and Clear Coast Consulting of Canada (“Bronozian Consultants”) were contracted by Mr. Harry Bronozian in April 2017 to evaluate the Amulsar Gold Project. The focus has been on the potential effects of the project on water resources, commonly the most critical and long-term environmental concern for large-scale metal mines. The overall purpose of the work was to provide a critical, detailed, and independent technical evaluation of the Amulsar Gold Project aimed at identifying the operational and long-term consequences of the proposed mine. The scope of work was to review all available Lydian and other documents associated with the project; examine their accuracy, completeness, and shortcomings; evaluate the potential for acid rock drainage (ARD) generation, the likelihood of impacts, and the reliability and effectiveness of proposed mitigation measures; and develop recommendations for further technical tasks if required. The reports and memoranda completed by the Bronozian Consultants have been distributed to Lydian International, the Armenian Ministry of Nature Protection, Armenian nonprofit organizations, and Armenian universities.

All the Bronozian Consultants have PhDs in disciplines relevant to this work and decades of individual experience in the evaluation of mining projects and their environmental effects. They have published regularly on topics related to the work and have taught courses in mine water treatment, geochemical characterization, environmental impact assessment evaluation, and mine operations and effects, among others. The review of the Amulsar Gold Project is based on their collective knowledge and experience and is supported by internationally recognized peer-reviewed scientific and technical references.

The evaluation has found that the Amulsar Gold Project, as proposed, poses a high risk of long-term, adverse impacts to the environment. Our strong recommendation to the government of Armenia and its citizens is that the mine not be developed until the identified shortcomings are corrected.

This final document by the Bronozian Consultants discusses the primary concerns and likely consequences of the proposed mine, and recommendations for addressing the concerns before mining begins. A list of all identified issues is provided in tabular form at the end of the document; the overview discusses the highest priority concerns, consequences, and recommendations. Appendix A contains a list of similar mines and their environmental impacts. The reports and memoranda produced by the Bronozian Consultants for the Amulsar Gold Project are listed in Appendix B, and the documents reviewed are listed in Appendix C.

2. Priority Concerns and Consequences

The many concerns and consequences of the Amulsar Gold Project identified by the evaluation are listed in Table 1. The potential consequences are similar for many of the issues identified: contamination of groundwater, springs, streams, and water in the Spandaryan-Kechut Tunnel and the Kechut Reservoir. Water and contaminant flow paths from the mine facilities to downgradient waters after the mine closes are shown in Figure 1, taken from the ESIA (Lydian International, 2016). The worst water quality is predicted for leachate from the waste rock facility (BRSF), which is upgradient of the tunnel, the Kechut Reservoir, and the Arpa River. Because tests were not conducted on the abundant mine wastes that will leach more acidity and higher metal concentrations, the impacts to
receptors, including aquatic life, will be more severe than predicted. Decreased flows in streams, springs, the tunnel, and the reservoir and lower groundwater levels due to pit dewatering and decreases in groundwater recharge caused by the presences of large waste and ore facilities covering the landscape have also been identified in the ESIA. Such decreases in water quality and clean water availability are highly problematic for an area that relies on clean and reliable water resources and that provides much of the country’s water supply to the Kechut Reservoir.

Figure 1. Groundwater flow paths during post-closure. Flow paths for water and contaminants from the barren rock storage facility (BRSF; waste rock dump), the heap leach facility (HLF; where gold is extracted from ore using a cyanide solution), and the open pits (Erato, Tigranes, Artavazdes; where ore and wastes are extracted) to the Arpa, Darb, and Vorotan rivers; springs; the Spandaryan-Kechut Tunnel; and the Kechut Reservoir are shown as colored lines (different colors for different mine sources). Flow paths from the Erato Pit (in yellow), which will not be backfilled, reach nearly all receptors, including the Arpa River upstream of the Kechut Reservoir. Gray numbered flow paths represent flow paths from the pits evaluated in Golder Associates (2014a). Note that the groundwater model used to identify the flow paths did not consider the abundant faults in the area that could bring contaminants more quickly, and with less dilution, to unanticipated receptor locations (Golder Associates, 2014b).

Source: Lydian International, 2016. Chapter 6.9, Figure 6.9.3.
The highest priority concerns and consequences for development of the Amulsar Gold Project, not necessarily in order of importance, are as follows:

- Contamination of downgradient groundwater, streams, springs, reservoir, tunnel from acid rock drainage and contaminant leaching that will last for centuries
- Decreased flow in springs, streams and decreased groundwater levels; underestimation of excess water volumes that will need to be treated during operations due to uncertainties in site-wide water balance
- Inadequate and incorrect geochemical evaluation of wastes and ore; underestimation of acid drainage and contaminant leaching potential of mined materials and negative impacts to the environment
- Inadequate ARD management plan based on poor geochemical evaluation and interpretation
- Incorrect Water Quality prediction model that fails to correctly predict water flows and chemistry, leading to ineffective mitigation measures
- Key measures proposed to mitigate ARD post-closure are untested
- Inappropriate water treatment system for mine-influenced waters during mining and long after mining ceases
- Lack of active treatment before Day 1 of mining
- Fast-tracking and inadequate financial assurance (only US $34 million) for a large-scale, high-risk mine operated by an inexperienced mining company, which risks premature abandonment; errors in the economic feasibility study (NI 43-101)
- Certain documents with key information are not publicly available.

### 3. Priority Recommendations

The highest priority recommendations include operating an active mine water treatment plant from before mining begins, conducting additional geochemical testing, changing the ARD management plan to minimize or eliminate ARD and contaminant release, requiring appropriate financial assurance, and creating an independent monitoring system. These changes, additions, evaluations, and improvements should be conducted before mining begins.

The highest priority recommendations for improving the Amulsar Gold Project, not necessarily in order of importance, are as follows:

- Design and build an active mine water treatment plant that will operate before Day 1 of mining and into closure that will be able to effectively treat ARD and other mine contaminants exceeding applicable standards
- Identify geochemical test units and conduct additional static, short-term, and long-term testing; select field and laboratory methods for identification and separation of PAG materials
- Revise predicted chemistry of mine-impacted waters and ARD management plan based on results of geochemical testing and a more robust adaptive management approach; reconsider placement and management of ore and waste materials
Revise predicted water chemistry at closure for each source (waste rock, reclaimed heap, pit discharge) and revise proposed post-closure mine water treatment to account for updated feed chemistry.

Improve the operational water balance estimate and recalculate excess water that will require treatment during mining.

Create an independent monitoring, evaluation, and training process that funds the involvement of the community and their independent expert advisors, with mandated annual reporting.

Require a bond/financial assurance that will cover mine closure costs if company leaves before remediation is complete; funding level should include costs for perpetual treatment of acid drainage (calculated for 200 years) and long-term monitoring and maintenance of mine facilities and water quality; an independent evaluation of the appropriate bond amount and type is needed.

4. Conclusion

The conclusion drawn by the Bronozian Consultants is that the high risk of acid drainage and contaminant leaching, the poor geochemical evaluation, the inadequate water quality predictions and mitigation measures, Lydian’s inexperience, and the insufficient financial guarantee combine to make this a high risk project during mining and for hundreds of years after operations cease. This conclusion directly contradicts the claims made for Lydian by AMC Consultants (Lydian International Limited, 2017), that: “AMC is unaware of any environmental, permitting, legal, title, taxation, socio-economic, marketing, political, or other relevant issues that may materially affect the Mineral Resources.” Such a statement is important for securing financing for the project, but it ignores the short-term and long-term liabilities predicted by the available evidence. The government and the people of Armenia should demand better from any company desiring to extract the country’s mineral wealth.

<tr>
<td>Waste Management</td>
<td>Use of UV rocks for construction</td>
<td>Long-term leaching of mine contaminants, including acid drainage, from construction fill</td>
<td>Identify non-reactive rocks within wastes and use only those for construction fill</td>
</tr>
<tr>
<td>Waste Management</td>
<td>Separation and special handling of reactive wastes relies on misinterpretation of ABA and HCT results</td>
<td>Material identified and used as NAG will produce acid and leach metal and other contaminants</td>
<td>Improve identification of PAG and NAG/unreactive rock, also taking into account acidity from sulfate minerals</td>
</tr>
<tr>
<td>Mitigation Measures</td>
<td>PAG material will not be placed deepest in pit; planned encapsulation of PAG will not prevent acid generation</td>
<td>Long-term acid generation and transport from pit backfill and waste rock facility</td>
<td>Segregate and store PAG waste and place deepest in Tig/Art pit; re-evaluate potential for flow-through pits and post-closure groundwater level in pits</td>
</tr>
<tr>
<td>Mitigation Measures</td>
<td>No commitment to revise the ARD Management Plan if mine life is expanded, mining proceeds through Lower Volcanics</td>
<td>Significantly more sulfides will be found in the Lower Volcanics; Lydian needs to make a commitment to review ARD Management Plan when it revises its mine plan</td>
<td>Lydian needs to commit to revising its ARD Management plan if it plans to mine into the Lower Volcanic</td>
</tr>
<tr>
<td>Mine Water Treatment</td>
<td>No active mine water treatment until after Year 4 of mining</td>
<td>Likely insufficient storage volume for contact water or extracted acidic groundwater potentially resulting in excess for internal use and discharge of untreated water to the environment</td>
<td>Design and build an active treatment plant on site that will begin operating before mining begins (during construction)</td>
</tr>
<tr>
<td>Mine Water Treatment</td>
<td>Use of passive treatment system during mine operations</td>
<td>Invalid design for acid drainage with high aluminum loads resulting in system failure</td>
<td>Redesign treatment system that accounts for more conservative water quality predictions</td>
</tr>
<tr>
<td>Mine Water Treatment</td>
<td>Use of passive treatment system during mine operations</td>
<td>Lack of design criteria for ammonia, arsenic, mercury or thiocyanate will result in lack of</td>
<td>Provide design basis and redesign treatment system</td>

Appendix A. Selected examples of Similar Mines to the Amulsar Gold Project and Consequences

The following mines represent a limited selection of mines that are similar to the Amulsar Gold Project in terms of size, mine type, and/or geochemical characteristics. Their consequences, references, and, where available, information on financial assurance and costs to remediate the mine after abandonment are provided. Comparisons show that the approximately $34 million reclamation bond for Amulsar would be inadequate to fully remediate the project, monitor water quality, and maintain environmental protection (including long-term water treatment) in the case of premature abandonment.

</tr>
</thead>
</table>
| Vangorda/Grum Mine, Faro, Yukon Territory, Canada; Curragh Resources Incorporated and Anvil Range Mining Corporation | Open-pit lead/zinc, flotation, waste rock piles | Company went bankrupt in 1998, and the Canadian Government took over reclamation and closure planning. Acid drainage was predicted and did occur. Seepage data from existing facilities underestimated future concentrations and loadings, while humidity cell leachate concentrations, which were higher, came closer to long-term actual concentrations. Costs for full reclamation of the mine are estimated at CDN $500 million. | 1. MEND, 2008: [http://mend-nedem.org/wp-content/uploads/2013/01/1.70.1.pdf](http://mend-nedem.org/wp-content/uploads/2013/01/1.70.1.pdf)  
| Nickel Plate Mine, British Columbia, Canada; Barrick Gold | Open-pit gold, flotation, tailings pond and waste rock piles | Thiocyanate was produced during gold cyanidation and built up to 1.4 g/L in reclaim water. A treatment plant has been operating to remove thiocyanate, ammonia, arsenic and nitrate from reclaim water since 1996 at an annual operating cost of US $4.87 million/year. | Given and Meyer, 1998: [https://goo.gl/wcgR3h](https://goo.gl/wcgR3h) |
| Zortman and Landusky, Montana, USA; Pegasus Gold Corporation | Open-pit gold and silver, cyanide heap leach | Severe acid drainage not predicted in original EIS. Unpermitted acid drainage discharges resulted in Montana Water Quality Act violations in several streams and effects on a nearby tribal community. In 1996, Pegasus was required to construct a water collection and treatment plant, pay penalties, bond for long-term operation and maintenance of the plant, conduct water quality studies, and improve water quality on the reservation. Pegasus then went bankrupt in 1998 and abandoned the site. The bond ($67 million) was insufficient to adequately reclaim the site. | 1. [http://leg.mt.gov/content/publications/environmental/2004zortman.pdf](http://leg.mt.gov/content/publications/environmental/2004zortman.pdf)  
<p>| Jerritt Canyon, Nevada, USA; Queenstake Resources | Open-pit and underground gold and silver; heap and vat leach processing | Cyanide, chloride, TDS, arsenic, sulfate plume in groundwater from tailings impoundment; TDS and sulfate exceedences in creeks from waste rock pile. EIS predicted no impacts from mining. Overestimated dilution; sample size/representation incorrect; waste rock mixing/segregation not effective; Liner leak, embankment failure or tailings spill. | <a href="https://www.earthworksaction.org/files/publications/ComparisonsReportFinal.pdf">https://www.earthworksaction.org/files/publications/ComparisonsReportFinal.pdf</a> (p. 150) |</p>
